Through this AI generated code, the main purpose was to clean the original dataset, set an encryption to preventing the release of sensitive patient information, along with removing the identification of the patients. While reviewing the code, I noticed a couple of issues causing the code to lack usability and to perform the intended functions. To begin with, I noticed that the security key code was in the wrong location, as it needed to follow the encryption key path within the same function. To fix this, I simply relocated the code to allow better flow and align the pathways; this created ease of readability and function within the code. While doing this, I also noticed that the security warning code caused an error when running. It was determined that due to the key path function ran outside of the main function, it was unable to locate the variables needed to complete the task of the warning code. To fix this issue, the key path was moved inside the main function, which solved the error. Lastly, I noticed issues with the missing values section of the code. Within this section, missing values were accounted for within the data set; however, a specific location to view output was missing. Along with this, I also noticed that the data only accounted for specific statistics. The data provided allowed for information on statistics like billing amounts to be included. I was able to include a section within the code that highlighted the billing amounts. With the statistics incorporated, along with missing values, the code was still missing a quality report. This quality report would locate the missing values and combine them within one section of the code, allowing increased readability. Within this quality report, the missing values were accounted for and totaled. But invalid billing amounts and ages were also accounted for. Overall, after reviewing the code, I understand that AI makes errors and can lack overall readability for a user. By reviewing the code, I was not only able to improve readability but also able to better execute the main functions described within the code.
